dimethyl ester of 2-methyl-2-carboxy-1,2,3,4-tetrahydro-
naphthalene-1-butyric acid as obtained from the reaction
was a liquid. From 5.52 g. of propionic acid ester was
obtained 4.56 g. (75%) of the product which "sublimed"
at 190–200° at 0.5 mm.

Four and six-tenths grams of the aforementioned ester
was cyclized in a nitrogen atmosphere by means of sodium
methoxide in exactly the same manner as described for the
previous cyclizations to give 11-methyl-1-keto-2-carbo-
methoxy-1,2,3,4,9,10,11,12-octahydrophenanthrene
(X),
which was a liquid at room temperature but which solidified
on standing at about −10°. The cyclized product which
was "sublimed" at 170–180° at 0.5 mm. was not obtained
analytically pure.

The cyclized keto-ester obtained above was hydrolyzed
in an atmosphere of nitrogen in the manner previously
described to give 1.9 g. (59% yield from the butyric ester)
of the methylketooctahydrophenanthrene which "sub-
limed" at 100–150° at 0.6 mm. The product was a
liquid which was not obtained analytically pure.

The semicarbazone of XI formed small colorless crystals;
m. p. 210.5–212.5° with decomposition in a preheated bath.

Summary

The synthesis of the cis and trans forms of
3'-keto-2-methyl-1,2-cyclopentano-1,2,3,4-tetra-
ydrophenanthene from 1-tetralone is described.
These compounds possess the B, C and D rings of
the sex hormone equilenin including the angular
methyl group, but lack the phenolic A
ring. In
addition, a homolog possessing a six-membered D
ring has been synthesized.

Some Fluorinated Amines of the Pressor Type

BY C. M. SUTER AND ARTHUR W. WESTON

The study of physiologically active compounds
containing fluorine in the aromatic nucleus has
now been extended to include a number of pressor
amines. m-Fluorophenethylamine and 3-fluoro-
4-hydroxyphenethylamine have been described
previously but their physiological action was not
reported. p-Fluorophenylpropanolamine has an
ephedrine-like action except that it probably
does not show tachyphylaxis.

p-Fluorophenethylamine and its N-methyl de-
rivatives were prepared from fluorobenzene by the
reactions indicated.

\[ \text{C}_{6}\text{H}_{4}\text{F} + \text{Br}_2 \rightarrow \text{p-BrC}_{6}\text{H}_{4}\text{F} \]

\[ \text{C}_{6}\text{H}_{4}\text{F} + \text{Mg} \rightarrow \text{C}_{6}\text{H}_{4}\text{Mg} \text{CH}_3 \]

The liquid dibromide that constitutes most of the
dibromide fraction obtained as a by-product in
the bromination of fluorobenzene is chiefly 2,4-
dibromofluorobenzene as shown by its synthesis
from 2,4-dibromoaniline. The solid isomer is
then probably 3,4-dibromofluorobenzene. p-Fluo-
rophenethyl alcohol has been obtained previously by
reduction of p-fluorobenzyl cyanide with sodium and alcohol
for a trace of p-fluorophenethylamine.

α-Methyl-p-fluorophenethylamine was pre-
pared from p-fluorobenzyl methyl ketone and
formamide. The ketone was obtained in 37% yield
by rearrangement of the addition product
obtained from chloroacetone and p-fluorophenyl-
magnesium bromide.

The physiological tests on the fluoroamines have produced some interesting results. The
toxicity of each amine hydrochloride was deter-
mined by oral administration in a 0.5% suspen-
sion of tragacanth to female white mice of the
Carworth strain. The toxicities of the unfluo-

at each dose level, with a sufficient number of levels to encompass the LD. 0 and LD. 100. The LD. 50 was calculated in each instance by the use of Behren’s method.

The effects of the amine hydrochlorides on blood pressure were determined in rabbits, dogs and guinea pigs. In general, the effect of the compounds was depressor in rabbits and pressor in dogs and guinea pigs. In the experiments with rabbits, although there was considerable variation, similar doses of N-methyl-p-fluorophenethylamine, α-methyl-p-fluorophenethylamine and α-methylphenethylamine showed the same depressor activity which was on the average greater than for p-fluorophenethylamine. In the experiments on dogs p-fluorophenethylamine, α-methyl-p-fluorophenethylamine and α-methylphenethylamine showed similar pressor activity while N-methyl-p-fluorophenethylamine was slightly less active. In the experiments on guinea pigs, α-methyl-p-fluorophenethylamine showed greater pressor activity than p-fluorophenethylamine, and N-methyl-p-fluorophenethylamine was more active than α-methylphenethylamine. Because of its low toxicity and its pressor activity N-methyl-p-fluorophenethylamine was the most promising of the compounds studied.

**Experimental**

**Bromination of Fluorobenzene.**—Bromination of 135.6 g. (1.41 moles) of fluorobenzene with 287 g. (1.70 moles) of bromine in the presence of iron filings2 gave besides 178 g. of the dibromofluorobenzene (22 mm.), 214.6' (745 mm.), d₂₀ 1.5840, d₁₀ 2.047, Mq calcd. 41.73, observed 41.51.

**p-Fluorophenethyl Alcohol.—**To a Grignard reagent prepared from 100 g. (0.571 mole) of p-bromofluorobenzene in 250 ml. of dry ether was added slowly a solution of 52.8 g. (1.2 mole) of ethylene oxide in 60 ml. of dry benzene from a dropping funnel surrounded by ice. The temperature of the reaction mixture was kept below 10° during the addition and was then raised slowly. At 45° a vigorous reaction occurred with separation of solid material. After two hours of refluxing the mixture was added to ice and dilute sulfuric acid. The benzene-ether layer was separated, combined with the ether extract of the aqueous layer, washed with water and sodium bicarbonate solution and dried. Fractionation of the ether layer gave 54.8 g. (68.5% yield) of product distilling at 114-122° (20 mm.), most of which came over at 117-118°. The properties of this fraction were n²₀ 1.5081, d₁₀ 1.173, Mq obsd. 36.76, calcd. 36.98. The alcohol has been reported6 as a colorless oil, b. p. 110° (20 mm.). Conversion of 0.5 g. of the alcohol to the benzoate gave a product melting at 54.5-55.5°. Previously4 this has been reported to have the m. p. 43-44°, and hence was analyzed.

**Anal.** Calcd. for C₆H₅BrO: C, 73.76; H, 5.36. Found: C, 73.73; H, 5.65.

**p-Fluorophenethyl Bromide.—**A procedure similar to that of Speer and Hill7 for phenethyl bromide was employed. To a stirred solution of 50 g. (0.4 mole) of p-fluorophenethyl alcohol in an equal weight of dry benzene kept in ice and salt was added slowly 54 g. (0.31 mole) of phosphorus tribromide. The mixture was heated slowly to 100° and then cooled, treated with ice water and then washed with bicarbonate solution and with water. There was obtained 65 g. (80% yield) of product, b. p. 101-102° (17 mm.), n²₀ 1.5323, d₁₀ 1.456, Mq calcd. 43.21, obsd. 43.31. Although this material had satisfactory physical constants the bromine analysis was low. It was used in the next experiment without further purification.

**Anal.** Calcd. for C₆H₅BrF: C, 73.76; H, 5.36. Found: C, 73.73; H, 5.65.

**p-Fluorophenethylamine.—**To 700 ml. of absolute alcohol containing about 112 g. (6.6 moles) of ammonia was added 20.3 g. (0.1 mole) of p-fluorophenethyl bromide. The alcohol solution was kept in a tightly stopped bottle at room temperature for ten days. The residue from evapo-

2. Analysis by Mr. E. Washburn of this Laboratory.
ration of the alcohol was treated with 10% sodium hydroxide, the amine extracted with ether and the solution dried with potassium hydroxide. Fractionation of the ether solution gave 9.8 g. of amine (68% yield) b. p. 99–100° (24 mm.), n D 1.5080, d 40. 1.069, M. D. calc. 38.86, obsd. 38.79. The residue from the distillation, probably secondary and tertiary amines, amounted to 4–5 g.

 Anal. Calcd. for C$_{8}$H$_{10}$NF: neut. eq., 139. Found: neut. eq., 138.3.

The hydrochloride was prepared by passing hydrogen chloride gas into a dry ether solution of the amine and crystallizing the precipitate from dry isopropyl alcohol. It is soluble in absolute ethanol and insoluble in acetone, chloroform and carbon tetrachloride. From 7.4 g. of amine there was obtained 6.3 g. of pure hydrochloride, silvery plates melting 188°.

 Anal. Calcd. for C$_{8}$H$_{10}$NF: neut. eq., 153. Found: neut. eq., 153.7, 153.3.

The hydrochloride was prepared as for that of p-fluorophenethylamine. After crystallization from acetone the m. p. was 163–104°.

N-Methyl-p-fluorophenethylamine.—To a solution of 20.3 g. (0.1 mole) of p-fluorophenethyl bromide in 15.5 g. of dry n-butyl alcohol in a magnesia citrate bottle was added 15.5 g. (0.5 mole) of dry methyamine gas. The bottle was stoppered and heated on the steam-bath for twenty-four hours, cooled and the contents made alkaline with 30% sodium hydroxide. The mixture was extracted three times with ether, the ether dried over potassium hydroxide and the solution fractionated. The product distilling at 105–107° (260–208°) amounted to 9 g. or 59% of the theoretical amount. Its properties were n D 1.4964, d 40. 1.027, M. D. calc. 43.96, observed 43.57.

 Anal. Calcd. for C$_{8}$H$_{10}$NCIF: Cl. 18.71. Found: Cl. 18.78, 18.75.

p-Fluorobenzyl Cyanide.—To a solution of 11 g. (0.24 mole) of sodium cyanide in 10 ml. of water was added 25.3 g. (0.173 mole) of crude p-fluorobenzyl chloride 44 b. p. 79–83° (22 mm.) dissolved in 25 g. of 95% alcohol. The mixture was refluxed for four hours, cooled, and the insoluble sodium chloride filtered off and washed with alcohol. The combined alcohol solutions were partially distilled and the residue and diluted alcoholic distillate extracted with ether. Fractionation of the dried ether solution gave 9.3 g. of nitrile distilling at 118–122° (20.5 mm.). A pure sample, b. p. 122–123° (21 mm.), had n D 1.5007, d 40. 1.139, M. D. calc. 34.98, obsd. 34.93.

 Anal. Calcd. for C$_{8}$H$_{10}$NF: N, 10.37. Found: N, 10.10.

Lower boiling fractions from the distillation contained a solid, m. p. 183–184°. p-Fluorobenzoic acid melts at 182–184°.

An attempt to reduce p-fluorobenzyl cyanide with sodium and alcohol according to the procedure of Adams and Marvel 45 gave only a little basic material which could not be purified.

p-Fluorobenzyl Methyl Ketone.—A Grignard reagent was prepared from 35 g. (0.20 mole) of p-fluorobromobenzene and 4.6 g. (0.19 mole) of magnesium. To this was added 18.5 g. (0.2 mole) of chloroacetone in 50 ml. of ether as rapidly as the refluxing of the reaction mixture would allow. The ether was removed by heating the reaction flask in an oil-bath and at 100° the residue foamed with formation of a gel from which ether was removed slowly by heating at 135–140° for forty-five minutes. The flask was cooled, ice and dilute acid were added, the heavy oil which separated was removed with ether and the ether solution dried and fractionated. There was obtained 11.2 g. (37%) of practically pure ketone distilling at 106–107° (18 mm.).

A variation of this procedure in which the reaction mixture was not heated above 100° gave a product that could not be satisfactorily fractionated. Substantially pure ketone was finally obtained by conversion to the sodium bisulfite addition compound followed by regeneration with dilute sodium carbonate. It distilled at 108° (18 mm.) as a light yellow oil with n D 1.4965, d 40. 1.107, M. D. calc. 40.07, obsd. 40.17. After a few days of standing, crystals of p-fluorobenzoic acid were deposited. Carbon and hydrogen analyses gave low results even with material kept in a sealed ampoule. A solid derivative was therefore prepared. The dinitrophenylhydrazone did not form but the semicarbazone, m. p. 200.5–201.5°, separated readily. Analysis by the Jamieson method 46 of titrating with potassium iodate gave only fair results.

 Anal. Calcd. for C$_{8}$H$_{10}$ON$_{3}$F: eq. wt., 52.30. Found: eq. wt., 51.50.

 Anal. Calcd. for C$_{8}$H$_{10}$ON$_{3}$F: eq. wt., 52.30. Found: eq. wt., 51.50.

In this analysis the end-point was not stable, probably due to the reaction of the liberated ketone with iodine.

α-Methyl-p-fluorophenethylamine.—A mixture of 8.7 g. (0.057 mole) of p-fluorobenzyl methyl ketone and 16 g. (0.36 mole) of formamide was heated in a 100-ml. round-bottomed flask attached to an air condenser for twelve hours at a temperature where vigorous bubbling occurred. 47 The amide was hydrolyzed by refluxing with 35 ml. of 30% sodium hydroxide for eleven hours, and the amine layer separated. Distillation gave 3.6 g. (41% yield) of pure amine, b. p. 95–96° (17 mm.). n D 1.4979, d 40. 1.028, M. D. calc. 43.49, observed 43.65. The amine rapidly took up carbon dioxide from the air forming a solid salt.

Anal. Calcd. for C$_{8}$H$_{10}$NF: neut. eq., 153. Found: neut. eq., 152.2, 152.4.

The amine was converted into the hydrochloride in the usual manner. After crystallizing from dry acetone it melted at 156–157°.

 Anal. Calcd. for C$_{8}$H$_{10}$NFCl: Cl. 18.71. Found: Cl. 18.73.

Summary

1. Three new fluorinated amines of the phenethylamine type have been prepared.

2. Physiological tests with white mice in-
cate that the fluorinated phenethylamines are slightly more toxic than the unsubstituted compounds. Toward dogs and guinea pigs the amines showed pressor activity while with rabbits the effect was depressor.

The Acid Catalyzed Esterification of Normal Fatty Acids

BY HILTON A. SMITH AND C. H. REICHARDT

In a recent article the study of the effect of the length of the carbon chain on the rate of the catalyzed esterification of normal aliphatic acids in dry methanol was reported. It was demonstrated that an increase in the hydrocarbon chain length of the acid from one to three carbon atoms caused a lowering of the value of the specific reaction rate constant, while further increase in the number of carbon atoms had no effect. It was further demonstrated that the activation energy is, within experimental error, the same (about 10,000 cal./mole) for all normal acids.

In a subsequent publication, Fairclough and Hinshelwood also reported a study of the esterification of normal fatty acids, including the catalyzed reaction in dry methanol. Their findings differ from those already published. Their activation energies are consistently higher by some 15–20%, and $E$ for the esterification of acetic acid is also considerably greater than for acids of larger molecular weight. Also, their results indicate that, instead of remaining the same with increasing chain length, the reaction velocity constants for esterification of butyric and higher acids go through a minimum at a chain length of approximately ten carbon atoms.

The high activation energies in general and also the low $k$'s for pelargonic acid as reported by Fairclough and Hinshelwood, are a direct result of their choice of the values of $r$ in Goldschmidt's equation

$$k = \frac{(a + r) \ln[a/(a - x)] - x}{r_i (\text{catalyst})}$$

(1)

where $a$ is the original concentration of organic acid, $x$ is the concentration of ester formed after time $t$, and the catalyst is hydrogen chloride. The constant $r$, although determined experimentally by choosing that figure which gives the most consistent reaction rate constants, is defined theoretically by the equation

$$r = \frac{(\text{CH}_3\text{OH}^+)(\text{H}_2\text{O})}{(\text{H}_2\text{O}^+)}$$

where $t_i$ is the specific reaction rate constant.
